1. Best-first search

- 2. Greedy best-first search
- 3. A\* search

- 4. Memory-bounded heuristic search
- 5. Heuristic functions

### Informed search strategies

#### Informed (heuristic) search strategies

- Use problem-specific knowledge beyond the definition of the problem itself
- Can find solutions more efficiently than can an uninformed strategy

#### What is heuristic

- Additional knowledge of the problem is imparted to the search algorithm.
- Heuristic **estimates** how close a state is to a goal.

#### **Best-first search**

#### Best-first search

Greedy best-first searce

A\* searc

Memorybounded heuristic search

Heurist

#### Best-first search

- An instance of the general **tree/graph search** algorithm
- A node is selected for expansion based on an **evaluation function**, f(n), which is construed as a cost estimate.
  - The node with the *lowest* evaluation f(n) is expanded first
  - The implementation of best-first graph search is identical to that for uniform-cost search, except for the use of f instead of g to order the priority queue
  - The choice of f determines the search strategy

#### Best-first search

Greedy best-first search

A\* searc

Memorybounded heuristic searc

Heuristi function

### Best-first search (cont.)

- Most best-first algorithms include as a component of f a **heuristic function**, denoted h(n):
  - h(n) estimated cost of the cheapest path from the state at node n to a goal state
- h(n) depends only on the state at node n
- Assumption of h
  - Arbitrary, nonnegative, problem-specific functions
  - Constraint: if n is a goal node, then h(n) = 0

# **Greedy best-first search**

### **Greedy best-first search**

- Try to expand the node that is **closest** to the goal, on the grounds that this is likely to lead to a solution guickly.
- Thus, it evaluates nodes by using just the heuristic function

$$f(n)=h(n)$$

#### **Illustration: Romania**

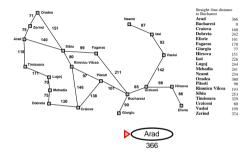

ullet Use the **straight-line distance** heuristic, which we will call  $h_{SLD}$ 

**Table 1:** Values of  $h_{SLD}$  – straight-line distances to Bucharest.

Arad	366	Mehadia	241

### **Properties**

- Complete: No, can get stuck in loops, e.g., find a path from lasi to Fagaras, lasi  $\rightarrow$  Neamt  $\rightarrow$  lasi  $\rightarrow$  Neamt  $\rightarrow$  ...
  - Yes in finite space with repeated-state checking
- **Time**:  $O(b^m)$ , but a good heuristic can give dramatic improvement
- **Space**:  $O(b^m)$ , keeps all nodes in memory
- Optimal: No

#### A\* search

### A\* search

- A\* search (pronounced A-star search) is the most widely known form of best-first search
- Ideas
  - Use heuristic to guide search, but not only
  - Avoid expanding paths that are already expensive
- Evaluation function

$$f(n) = g(n) + h(n)$$

- g(n): cost so far to reach n
- h(n): estimated cost of the cheapest path to goal from n
- f(n): estimated cost of the cheapest solution through n
- The algorithm is identical to UNIFORM-COST-SEARCH except that A\* uses g + h instead of g

#### A\* search

Memorybounded heuristic search

Heuristi function

### **Properties**

- **Complete** Yes, unless there are infinitely many nodes with  $f \leq f(G)$
- **Time** Exponential in [relative error in  $h \times length$  of soln.]
- **Space** Keeps all nodes in memory
- **Optimal** Yes, cannot expand  $f_{i+1}$  until  $f_i$  is finished
  - A\* expands all nodes with  $f(n) < C^*$
  - A\* expands some nodes with  $f(n) = C^*$
  - A\* expands no nodes with  $f(n) > C^*$

# Conditions for optimality: Admissibility and consistency

#### Concept 1

h(n) is an **admissible** heuristic

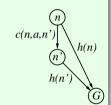

- if it never overestimates the cost to reach the goal
- or if for every node n,  $h(n) \leq h^*(n)$  ( $h^*(n)$  is a the true optimal cost to reach the goal state from n)
- An example of an admissible heuristic is the straight-line distance  $h_{SLD}$  that we used in getting to Bucharest

Heuristic function

# Conditions for optimality: Admissibility and consistency (cont.)

#### Concept 2

h(n) is an **consistent** heuristic if for every node n and every successor n' of n generated by any action a, the estimated cost of reaching the goal from n is no greater than the step cost of getting to n' plus the estimated cost of reaching the goal from n'

$$h(n) \le c(n, a, n') + h(n')$$

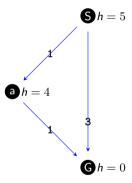

• Consistent heuristic is also admissible

Heuristi function

### Optimal for A\*

• Using tree search algorithm to find a path from S to G

# Optimal for A\* (cont.)

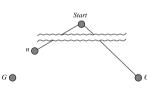

#### Theorem 1

The **tree-search version** of  $A^*$  is optimal if h(n) is admissible

#### **Proof**

Suppose some suboptimal goal  $G_2$  has been generated and is in the frontier. Let n be an unexpanded node on a shortest path to an optimal goal G (graph separation)

- f(G) = g(G) since h(G) = 0
- $f(G_2) = g(G_2)$  since  $h(G_2) = 0$
- $g(G_2) > g(G)$  since  $G_2$  is suboptimal
- f(G) > f(n) since h is admissible
- Since  $f(G_2) > f(n)$ , A\* will never select  $G_2$  for expansion

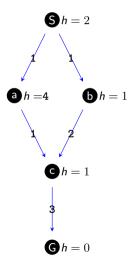

#### A\* search

# Optimal for A\* (cont.)

• Using graph search algorithm to find a path from S to G

### Optimal for A\* (cont.)

#### Theorem 2

The **graph-search version** of  $A^*$  is optimal if h(n) is consistent

#### Proof

• if h(n) is consistent, then the values of f(n) along any path are nondecreasing. Suppose n' is a successor of n; then g(n') = g(n) + c(n, a, n') for some action a, and we have

$$f(n') = g(n') + h(n') = g(n) + c(n, a, n) + h(n') \ge g(n) + h(n) = f(n)$$

• Whenever A\* selects a node n for expansion, the optimal path to that node has been found. Were this not the case, there would have to be another frontier node n' on the optimal path from the start node to n;  $f(n') < f(n) \Rightarrow n'$  would have been selected first.

#### A\* search

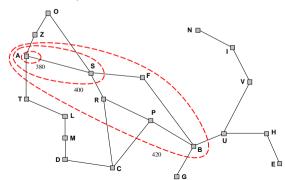

Memorybounded heuristic search

Heuristi

#### Contours

- ullet Search algorithm expands nodes in order of increasing f value
- We can draw contours in the state space, just like the contours in a topographic map
  - Gradually adds "f-contours" of nodes, contour i has all nodes with  $f < f_i$ , where  $f_i < f_{i+1}$

Best-firs search

Greedy best-first sear

#### A\* search

Memorybounded heuristic search

Heuristi function

# Contours (cont.)

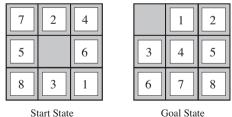

- The bands of uniform-cost search will be "circular" around the start state.
- The bands of A\* with more accurate heuristics will stretch toward the goal state and become more narrowly focused around the optimal path

Heuristic functions

#### The 8-puzzle

- The average solution cost for a randomly generated 8-puzzle instance is about 22 steps
- The branching factor b is about 3
- 8-puzzle:
  - $3^{22} \approx 3.1 \times 10^{10}$  states (using an exhaustive tree search)
  - 9!/2 = 181,440 reachable states (using graph search)
- 15-puzzle: around  $10^{13}$  states

**Figure 1:** A typical instance of the 8-puzzle. The optimal solution is 26 steps long.

Heuristic

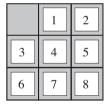

#### Admissible heuristics for 8-puzzle

- $h_1$  = the number of misplaced tiles.  $h_1$  is an admissible heuristic because it is clear that any tile that is out of place must be moved at least once
- $h_2$  = the sum of the distances of the tiles from their goal positions.  $h_2$  is also admissible because all any move can do is move one tile one step closer to the goal

Goal State

• 
$$h_1 = 1 + 1 + 1 + 1 + 1 + 1 + 1 + 1 + 1 = 8$$
 and  $h_2 = 3 + 1 + 2 + 2 + 2 + 3 + 3 + 2 = 18$

### Memory-bound heuristic search

- In practice, A\* usually runs out of space long before it runs out of time
- **Idea**: try something like DFS, but not forget everything about the branches we have partially explored

Greedy best-first searce

A\* searc

Memorybounded heuristic search

Heuristi function

# Iterative-deepening A\* (IDA\*)

- The main difference with IDS
  - Cut-off use the f-value (g + h) rather than the depth
  - At each iteration, the cutoff value is the smallest f-value of any node that exceeded the cutoff on the previous iteration
- Avoid the substantial overhead associated with keeping a sorted queue of nodes.
- Practical for many problems with unit step costs, yet difficult with real valued costs

Heuristi

# Recursive best-first search (RBFS)

- Keep track of the *f*-value of the best alternative path available from any ancestor of the current node
  - backtrack when the current node exceeds f\_limit
- As it backtracks, replace f-value of each along the path with the best value f(n) of its children

Greedy best-first searc

A\* searc

Memorybounded heuristic search

Heuristic

# Algorithm

```
function Recursive-Best-First-Search(problem)
returns a solution, or failure
  return RBFS(problem, MAKE-NODE(problem.INITIAL-STATE), ∞)
function RBFS(problem, node, f_limit)
returns a solution, or failure and a new f-cost limit
  if problem.GOAL-TEST(node.STATE) then return SOLUTION(node)
  successors \leftarrow \emptyset
  for each action in problem.Actions(node.State) do
    add CHILD-Node(problem, node, action) into successors
  if successors is empty then return failure,\infty
  for each s in successors do
    # update f with value from previous search, if any
    s.f \leftarrow \text{Max}(s.g + s.h, node.f)
  loop do
    best ← lowest f-value node in successors
    if best.f > f_limit then return failure, best.f
    alternative \leftarrow the second-lowest f-value among successors
    result, best. f \leftarrow RBFS(problem, best, MIN(f_limit, alternative))
    if result \neq failure then return result
```

Memorybounded heuristic search

Heuristic

#### Illustration

Stages in an RBFS search for the shortest route to Bucharest. The f-limit value for each recursive call is shown on top of each current node, and every node is labeled with its f-cost.

- (a) The path via Rimnicu Vilcea is followed until the current best leaf (Pitesti) has a value that is worse than the best alternative path (Fagaras).
- (b) The recursion unwinds and the best leaf value of the forgotten subtree (417) is backed up to Rimnicu Vilcea; then Fagaras is expanded, revealing a best leaf value of 450. (c) The recursion unwinds and the best leaf value of the forgotten subtree (450) is backed up to Fagaras; then Rimnicu Vilcea is expanded. This time, because the best alternative path (through Timisoara) costs at least 447, the expansion continues to Bucharest.

A\* searc

Memorybounded heuristic search

Heuristi function

# **Properties**

#### Optimality

• Like A\*, optimal if h(n) is admissible

#### Time complexity

- Difficult to characterize
- Depends on accuracy of h(n) and how often best path changes
- Can end up "switching" back and forth

#### Space complexity

- Linear time: O(bd)
- ullet Other extreme to  $A^*$  uses too little memory even if more memory were available

Heuristi

# (Simplified) Memory-bound A\* - (S)MA\*

- Similar to A\*, but delete the worst node (largest f-value) when memory is full
- SMA\* also backs up the value of the forgotten node to its parent.
  - If there is a tie (equal f-values), delete the oldest nodes first
- Simplified-MA\* finds the **optimal reachable solution** given the memory constraint.
  - The depth of the shallowest goal node, is less than the memory size (expressed in nodes)
- Time can still be exponential.

Greedy best-first searc

A\* searc

Memorybounded heuristic search

Heuristi

#### Learning to search better

- Could an agent learn how to search better? Yes
- Metalevel state space: in which each state captures the internal (computational) state of a program that is searching in an object-level state space.
- A **metalevel learning algorithm** learn from these experiences to avoid exploring unpromising subtrees
- For example, the map of Romania problem
  - The internal state of the A\* algorithm is the current search tree.
  - Each action in the metalevel state space is a computation step that alters the internal state; for example, each computation step in A\* expands a leaf node and adds its successors to the tree

#### **Heuristic functions**

Heuristic functions

#### Goal fixed?

- Assume that the goal state G is fixed
- Using Uniform-Cost-Search to find the shortest path from G to the other states
- The final g values can be considered as h values

Greedy best-first sear

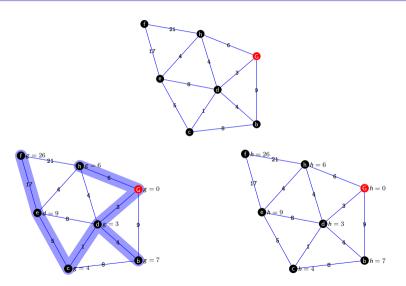

A\* searc

Memorybounded heuristic searc

Heuristic functions

# Goal fixed? (cont.)

## The effect of heuristic accuracy on performance

- **Effective branching factor**  $b^*$  characterize the quality of a heuristic.
- If the total number of nodes generated by  $A^*$  for a particular problem is N and the solution depth is d, then  $b^*$  is the branching factor that a uniform tree of depth d would have to have in order to contain N+1 nodes

$$N + 1 = 1 + (b^*) + (b^*)^2 + \dots + (b^*)^d$$

- b\* varies across problem instances, but fairly constant for sufficiently hard problems
- A well-designed heuristic would have a value of  $b^*$  close to  $1\Rightarrow$  fairly large problems solved at reasonable cost

Heuristic functions

# The effect of heuristic accuracy on performance (cont.)

d	Search Cost (nodes generated)			Effective Branching Factor		
	IDS	$A*(h_1)$	$A*(h_2)$	IDS	$A*(h_1)$	$A^*(h_2)$
2	10	6	6	2.45	1.79	1.79
4	112	13	12	2.87	1.48	1.45
6	680	20	18	2.73	1.34	1.30

18	_	3056	363	_	1.46	1.26
20	_	7276	676	_	1.47	1.27
22	_	18094	1219	_	1.48	1.28
24	_	39135	1641	_	1.48	1.26

Table 2: Comparison of the search costs and effective branching factors for the IDS and A\* algorithms with  $h_1$ ,  $h_2$ . Data are averaged over 100 instances of the 8-puzzle for each of various solution lengths d.

#### Heuristic functions

#### **Dominance and Composite**

- If  $h_2(n) > h_1(n)$  for all n (both admissible) then  $h_2$  dominates  $h_1$  and is better for search
  - A\* using  $h_2$  will never expand more nodes than A\* using  $h_1$
- Hence, it is generally better to use a heuristic function with higher values. provided it is consistent and that the computation time for the heuristic is not too long.
- Given a collection of admissible heuristics  $\{h_1, ..., h_m\}$  is available for a problem and none of them dominates any of the others.
- The **composite heuristic function** is defined as

$$h(n) = \max\{h_1(n), \ldots, h_m(n)\}\$$

is consistent and dominates all component heuristics

Best-first

Greedy best-first sear

A\* sear

Memorybounded heuristic search

Heuristic functions

## Generating admissible heuristics from relaxed problems

- A problem with fewer restrictions on the actions is called a **relaxed problem**.
- The state-space graph of the relaxed problem is a **supergraph** of the original state space because the removal of restrictions creates added edges in the graph.

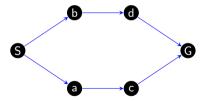

Figure 2: Original problem state-space

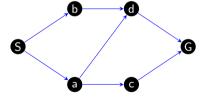

Figure 3: Relaxed problem state-space

Best-first

Greedy best-first sear

A\* sear

Memorybounded heuristic search

Heuristic functions

# Generating admissible heuristics from relaxed problems (cont.)

- Hence, the cost of an optimal solution to a relaxed problem is an admissible heuristic for the original problem.
- Furthermore, because the derived heuristic is an exact cost for the relaxed problem, it must obey the triangle inequality and is therefore **consistent**.

Greedy best-first sear

A\* searc

Memorybounded heuristic search

Heuristic functions

# Generating admissible heuristics from relaxed problems (cont.)

# 0.00

#### Original problem of 8 puzzle

 A tile can move from square A to square B if A is horizontally or vertically adjacent to B and B is blank

We can generate three relaxed problems by removing one or both of the conditions

#### **Relaxed problems**

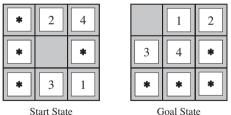

- **1.** A tile can move from square A to square B if A is adjacent to B  $\rightarrow h_2$
- 2. A tile can move from square A to square B if B is blank  $\rightarrow$  exercise
- **3.** A tile can move from square A to square  $\mathsf{B} o h_1$

Heuristic functions

#### **Generating admissible heuristics from subproblems**

- Admissible heuristics can also be derived from the solution cost of a subproblem of a given problem
  - The cost of the optimal solution of this subproblem ≤ the cost of the original problem (lower bound).
  - More accurate than Manhattan distance in some cases

**Figure 4:** A subproblem of the 8-puzzle instance. The task is to get tiles 1, 2, 3, and 4 into their correct positions, without worrying about what happens to the other tiles.

Best-first

Greedy best-first searce

A\* searc

Memorybounded heuristic search

Heuristic functions

#### Pattern databases

- Pattern databases (PDB) where store the exact solution costs for every possible subproblem instance
  - E.g., every possible configuration of the four tiles and the blank
- The database itself is constructed by searching back from the goal and recording the cost of each new pattern encountered; the expense of this search is amortized over many subsequent problem instances
- The complete heuristic is constructed using the patterns in the databases

Greedy best-first sear

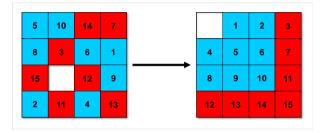

A\* searc

Memorybounded heuristic searce

Heuristic functions

#### **Computing the Heuristic**

- 31 moves needed to solve red tiles
- 22 moves need to solve blue tiles
- Overall heuristic is maximum of  $31 = \max(31, 22)$  moves

Best-first

Greedy best-first searc

A\* searc

Memorybounded heuristic search

Heuristic functions

#### Disjoint pattern databases

- $\bullet$  Limitation of traditional PDB: Take max  $\rightarrow$  diminish returns on additional PDBs
- **Disjoint pattern databases**: Count only moves of the pattern tiles, ignoring non-pattern moves.
- If no tile belongs to more than one pattern, add their heuristic values.

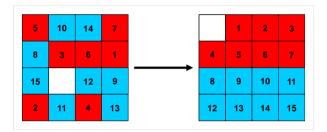

## **Computing the Heuristic**

A\* searc

bounded
heuristic searce

Heuristic functions

- 20 moves needed to solve red tiles
- 25 moves needed to solve blue tiles
- Overall heuristic is sum, or 45 = 20 + 25 moves

Greedy best-first sear

A\* searc

Memorybounded heuristic search

Heuristic functions

#### **Performance**

#### 15 Puzzle

- ullet 1000 imes speedup vs. Manhattan distance
- IDA\* with the two DBs (the 7-tile database contains 58 million entries and the 8-tile database contains 519 million entries) solves 15-puzzles optimally in 30 milliseconds

#### 24 Puzzle

- ullet 12 million imes speedup vs. Manhattan distance
- IDA\* can solve random instances in 2 days.
- Requires 4 DBs (each DB has 128 million entries)
- Without PDBs: 65,000 years

## Learning heuristics from experience

- Experience means solving a lot of instances of a problem.
  - E.g., solving lots of 8-puzzles
- Each optimal solution to a problem instance provides examples from which h(n) can be learned
- Learning algorithms
  - Neural nets
  - Decision trees
  - Inductive learning
